Example 6.8: An electrical firm manufactures light bulbs that have a life, before burn-out, that is normally distributed with **mean equal to 800 hours** and a **standard deviation of 40 hours**. Find the probability that a bulb burns between 778 and 834 hours. Also implement it in Python.

Solution:

$\mu = 800$ and $\sigma = 40$

$$Z_1 = \frac{778 - 800}{40} = -0.55$$

$$Z_2 = \frac{834 - 800}{40} = 0.85$$

$$\begin{aligned} P(778 \leq X \leq 834) &= P(-0.55 \leq Z \leq 0.85) \\ &= P(Z \leq 0.85) - P(Z \leq -0.55) \\ &= 0.8023 - 0.2912 \\ &= 0.5111 \end{aligned}$$

```
from scipy.stats import norm
```

Given data

```
mean = 800
```

```
std_dev = 40
```

```
lower_bound = 778
```

```
upper_bound = 834
```

Calculate z-scores

```
z_lower = (lower_bound - mean) / std_dev
```

```
z_upper = (upper_bound - mean) / std_dev
```

Find the probability using the cumulative distribution function (CDF)

```
probability = norm.cdf(z_upper) - norm.cdf(z_lower)
```

Print the result

```
print(f"The probability that a bulb burns between {lower_bound} and {upper_bound} hours is: {probability:.4f}")
```

Example 6.9: In an industrial process, the diameter of a ball bearing is an important measurement. The buyer sets specifications for the diameter to be **2.99** to **3.01**. The implication is that no part falling outside these specifications will be accepted. It is known that in the process the diameter of a ball bearing has a normal distribution with mean $\mu = 3.0$ and standard deviation $\sigma = 0.005$. On average, how many manufactured ball bearings will be scrapped? Also implement it in Python.

Solution:

$\mu = 3.00$ and $\sigma = 0.005$

$$Z_1 = \frac{2.99 - 3.00}{0.005} = -2.0$$

$$Z_2 = \frac{3.01 - 3.0}{0.005} = +2.0$$

$$\begin{aligned} P(2.99 \leq X \leq 3.01) &= P(-2 \leq Z \leq 2) \\ &= P(Z \leq 2) - P(Z \leq -2) \\ &= 0.9772 - 0.0228 \\ &= 0.9544 \end{aligned}$$

Required probability = $1 - P(2.99 \leq X \leq 3.01) = \mathbf{0.0456}$.

OR

From Table A.3, $P(Z < -2.0) = 0.0228$. Due to symmetry of the normal distribution, we find that $P(Z < -2.0) + P(Z > 2.0) = 2(0.0228) = \mathbf{0.0456}$.

```
from scipy.stats import norm
```

Given data

```
mean_diameter = 3.0
```

```
std_dev_diameter = 0.005
```

```
lower_specification = 2.99
```

```
upper_specification = 3.01
```

Calculate the z-scores for the lower and upper specifications

```
z_lower = (lower_specification - mean_diameter) / std_dev_diameter
```

```
z_upper = (upper_specification - mean_diameter) / std_dev_diameter
```

Calculate the probability of scrapping for a single ball bearing

```
prob_scrapped_single = norm.cdf(z_lower) + (1 - norm.cdf(z_upper))
```

Assuming a total production of 1 for simplicity, calculate the average number of scrapped ball bearings

```
average_scrapped = 1 * probab_scrapped_single
```

Print the result

```
print(f"On average, {average_scrapped:.2f} manufactured ball bearings will be scrapped.")
```

Example 6.10: Gauges are used to reject all components for which a certain dimension is not within the specification $1.50 \pm d$. It is known that this measurement is normally distributed with mean **1.50** and standard deviation **0.2**. Determine the value **d** such that the specifications “cover” **95%** of the measurements. Also implement it in Python.

Flowchart for Computing Probability

Flowchart for Computing x (Inverse Problem)

Solution: $\mu = 1.5$ and $\sigma = 0.2$

From Table A.3 we know that

$$P(Z < -1.96) = 0.0250$$

$$\therefore \frac{0.05}{2} = 0.0250$$

$P(Z > 1.96) = 0.0250$ (Due to symmetry of normal curve)

$$P(Z < 1.96) = 0.9750$$

$$\therefore 1 - 0.0250 = 0.9750$$

$$\Rightarrow P(-1.96 < Z < 1.96) = 0.95$$

$$\therefore P(Z > 1.96) = 0.0250$$

$$z = \frac{x - \mu}{\sigma} \Rightarrow x = \mu + \sigma z$$

$$x = \mu + \sigma z$$

$$\text{Let } x = 1.50 + d$$

$$\Rightarrow 1.50 + d = 1.50 + 0.2(1.96)$$

$$\Rightarrow d = 0.392$$

$$x_1 = \mu - d = 1.50 - 0.392 = 1.108$$

$$x_2 = \mu + d = 1.50 + 0.392 = 1.892$$

OR

$$x = \mu + \sigma z$$

$$\text{Let } x = 1.50 - d$$

$$\Rightarrow 1.50 - d = 1.50 + 0.2(-1.96)$$

$$\Rightarrow d = 0.392$$

$$x_1 = \mu - d$$

$$x_1 = 1.50 - 0.392 = 1.108$$

$$x_2 = \mu + d$$

$$x_2 = 1.50 + 0.392 = 1.892$$

```
import scipy.stats as stats
```

```
# Given data
```

```
mean = 1.50
```

```
std_deviation = 0.2
```

```
coverage = 0.95
```

```
# Find the z-score corresponding to the desired coverage
```

```
# Since it's two-tailed, we want the middle 95%, so the remaining is
```

```
#  $(100 - 95) / 2 = 2.5\%$  on each tail
```

```
area_in_tail = (1 - coverage) / 2
```

```
# Find the z-score for the area in the tail
```

```
z_score = stats.norm.ppf(1 - area_in_tail)
```

```
# Calculate d
```

```
d = z_score * std_deviation
```

```
# Print the result
```

```
print(f"The value of d such that 95% of the measurements are within  
1.50 +- d is {d:.3f}")
```

Example 6.11: A certain machine makes electrical resistors having a mean resistance of **40** ohms and a standard deviation of **2** ohms. Assuming that the resistance follows a normal distribution and can be measured to any degree of accuracy, what percentage of resistors will have a resistance exceeding **43** ohms? Also implement it in Python.

Solution:

$$P(X > 43) = ?$$

$$\mu = 40 \text{ and } \sigma = 2$$

$$z = \frac{43 - 40}{2} = 1.5$$

$$\begin{aligned} P(X > 43) &= P(Z > 1.5) \\ &= 1 - P(Z < 1.5) \\ &= 1 - 0.9332 \\ &= 0.0668 \text{ Or } \mathbf{6.68 \%} \end{aligned}$$

```
import scipy.stats as stats
```

Given data

```
mean_resistance = 40
```

```
std_dev_resistance = 2
```

```
resistance_threshold = 43
```

Calculate the z-score

```
z_score = (resistance_threshold - mean_resistance) /  
std_dev_resistance
```

Calculate the percentage of resistors exceeding 43 ohms

```
percentage_exceeding = (1 - stats.norm.cdf(z_score)) * 100
```

Print the result

```
print(f"The percentage of resistors with resistance exceeding 43  
ohms is: {percentage_exceeding:.2f}%")
```

Example 6.13: The average grade for an exam is **74**, and the standard deviation is **7**. If **12%** of the class is given **As**, and the grades are curved to follow a normal distribution, what is the **lowest possible A** and the **highest possible A⁻¹**? Also implement it in Python.

Solution:

$$\mu = 74 \text{ and } \sigma = 7$$

$$P(Z < z) = 0.88$$

$$P(Z < 1.18) = 0.88$$

$$x = \sigma z + \mu$$

$$x = (7)(1.18) + 74 = 82.26.$$

Therefore, the lowest **A is 83** and the highest **A^{-1} is 82**.

```
import scipy.stats as stats
import math

# Given data
mean_grade = 74
std_deviation = 7

# Find the z-score corresponding to the 88th percentile for A
percentile_A = 88
z_score_A = stats.norm.ppf(percentile_A / 100)

# Calculate the actual grade cutoff for A
grade_cutoff_A = math.floor(mean_grade + z_score_A * std_deviation)

# Calculate the actual grade cutoff for A-
grade_cutoff_A_minus = math.ceil(mean_grade + z_score_A *
std_deviation)

# Print the results
print(f"The lowest possible A is {grade_cutoff_A:.2f}")
print(f"The highest possible A- is {grade_cutoff_A_minus:.2f}")
```

Percentiles

A **percentile** is a marker on a normal curve such that the **marker is greater than or equal** to that percentage of results.

For example, suppose you are at the **30th percentile** for **how fast you type**. This means that you can type faster than **30% of all people**. The percentile can also be thought of as the **percent of area** to the **left of its marker**.

The shaded area to the left of the marker represents 30% of the normal curve.

Marker for the 30th percentile

Example Suppose the **mean length** of the hair of 10th grade girls is **10 inches** with a **standard deviation of 4** inches. At **what percentile** for hair length is a 10th grade girl if her hair is **17 inches long**? Also implement it in Python.

Solution

$$\mu = 10 \text{ and } \sigma = 4$$

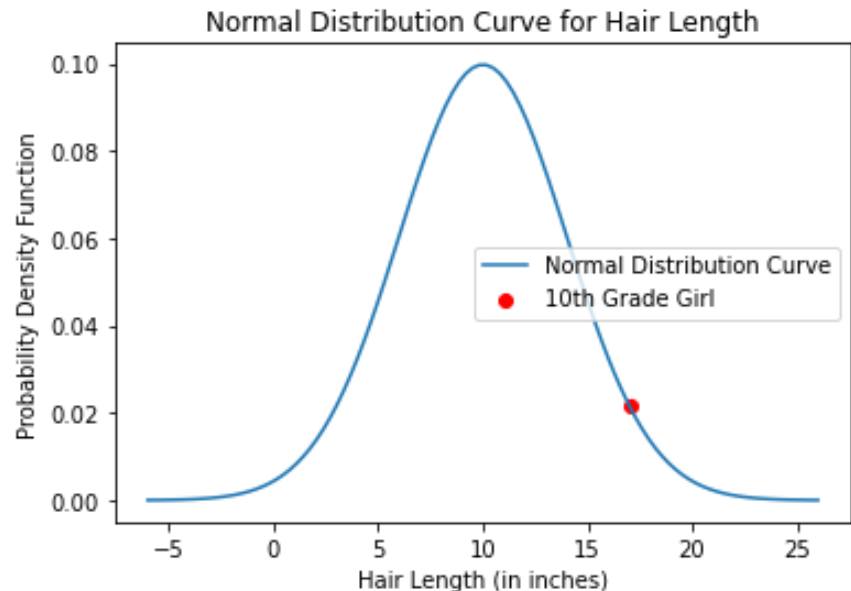

$$x = 17$$

$$P(X < 17) = ?$$

$$z = \frac{17 - 10}{4} = 1.75$$

$$P(X < 17) = P(Z < 1.75) \\ = 0.9599.$$

This tells us the girl is at about the **96th percentile** for hair length. In other words, this girl's hair is longer than 96% of all 10th grade girls

```
import scipy.stats as stats
```

Given data

```
mean_hair_length = 10  
std_dev_hair_length = 4  
girl_hair_length = 17
```

Calculate the z-score

```
z_score = (girl_hair_length - mean_hair_length) / std_dev_hair_length
```

Calculate the percentile using the CDF

```
percentile = stats.norm.cdf(z_score) * 100
```

Print the result

```
print(f"A 10th-grade girl with a hair length of 17 inches is at the  
{percentile:.2f}th percentile.")
```

Example 6.14: Refer to Example 6.13 and find the sixth decile.

Solution: The sixth decile, written D_6 , is the x value that leaves **60%** of the area to the left, as shown in Figure 6.21.

$$P(Z < z) = 0.6$$

$$P(Z < 0.25) = 0.6$$

$$z = 0.25.$$

$$D_6 = \sigma z + \mu$$

$$D_6 = (7)(0.25) + 74 = 75.75.$$

$$\text{Hence, } D_6 = 75.75.$$

That is, **60% of the grades are 75 or less**

Example: The scores on a national achievement exam are normally distributed with a **mean** of **500** and a **standard deviation** of **100**. If a student is selected at random, find the probability that the student scored **below 680**. Also implement it in Python.

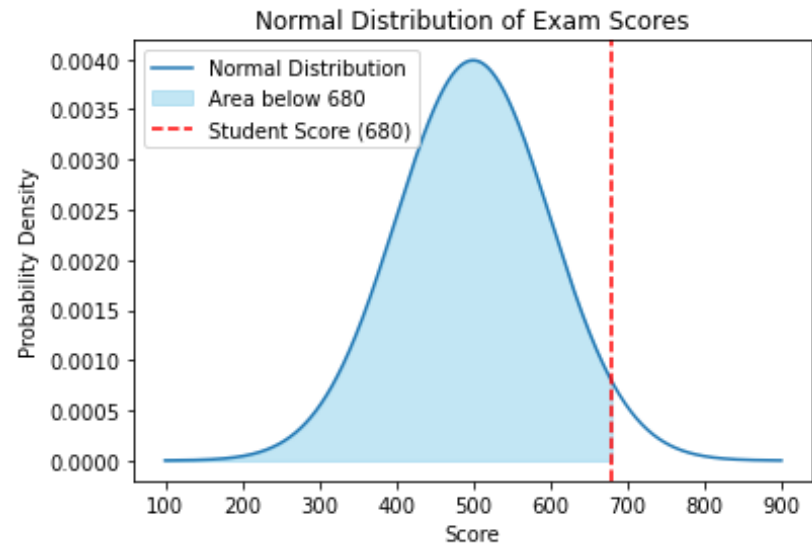

Solution:

$\mu = 500$ and $\sigma = 100$

Find the z value for 680:

$$z = \frac{680 - 500}{100} = 1.8$$

$$P(X < 680) = P(Z < 1.8) = .9641$$

```
import scipy.stats as stats
```

Given data

```
mean_score = 500
```

```
std_dev_score = 100
```

```
student_score = 680
```

Calculate the probability using the CDF

```
probability_below_680 = stats.norm.cdf(student_score, mean_score,  
std_dev_score)
```

Print the result

```
print(f"The probability that a randomly selected student scored below  
680 is: {probability_below_680:.4f}")
```
